A brief introduction to LATEXdocument preparation system

D.V. Fedorov

Abstract

We show some basic capabilities of LATEX: math, figures, references, citations, and sections.

1 Math

The gamma-function, denoted Γ, is usually defined via the following integral,

$$\Gamma(z) = \int_0^\infty x^{z-1} e^{-x} dx \ . \tag{1}$$

One of many simple approximation to the integral (1) is the Gergo Nemes asymptotic formula [1],

$$\Gamma(z) \approx \sqrt{\frac{2\pi}{z}} \left(\frac{1}{e} \left(z + \frac{1}{12z - \frac{1}{10z}} \right) \right)^z \ . \tag{2}$$

2 Figures

Here is an illustration of the Nemes' formula, compared with the built-in gamma function from the standard C-library. First, figure (1) shows the "latex" terminal of Gnuplot. Then, figure (2) shows the "pdf" terminal of Pyxplot.

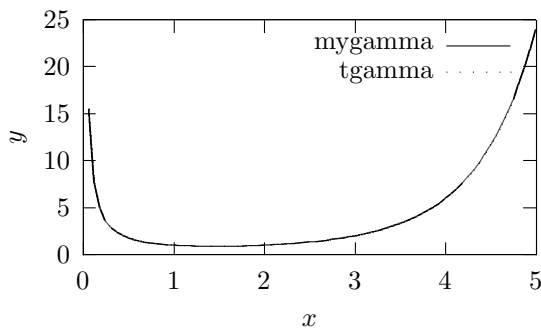

Figure 1: Nemes formula (2) via gnuplot "latex" terminal.

Figure 2: Nemes formula (2) via pyxplot "pdf" terminal.
